

[FOREWORD](#)

[INTRODUCTION](#)

[GLUCIDYL METHACRYLATE](#)
CAS N°: 106-91-2

COVER PAGE
SIDS Initial Assessment Report
for
10th SIAM
(Japan, March 15-17, 2000)

Chemical Name: Glycidyl methacrylate
CAS No: 106-91-2
Sponsor Country: Japan and United States

National SIDS Contact Point in Sponsor Country: Mr. Kazuhide Ishikawa
Ministry of Foreign Affairs, Japan
Mr. Oscar Hernandez
US EPA

HISTORY:

SIDS Testing Plan were reviewed in SIDS Review Process, where the following SIDS Testing Plan was agreed:

no testing ()
testing (X) Water solubility, Vapour pressure, Octanol/water partition coefficient, Stability in water, Biodegradation
Chronic toxicity to daphnia
Combined repeat dose and reproductive toxicity,
Chromosomal aberration test in vitro, Micronucleus test in vivo

Deadline for circulation: November 30, 1999

Date of Circulation: December 20, 1999

(To all National SIDS Contact Points and the OECD Secretariat)

SIDS INITIAL ASSESSMENT PROFILE

| | |
|---|--|
| CAS NO. | 106-91-2 |
| CHEMICAL NAME | Glycidyl methacrylate |
| STRUCTURAL FORMULA |  |
| <u>RECOMMENDATION</u> | |
| The chemical is a candidate for further work. | |
| <u>SUMMARY CONCLUSIONS OF THE SIAR</u> | |
| Human Health Hazards | |
| <p>Acute lethal toxicity of glycidyl methacrylate is low via the oral administration route. No mortality was observed in rats following inhalation exposure up to 2,394 mg/m³, the highest practically attainable vapor concentration. This chemical is considered both highly irritating (including necrosis, degeneration and hyperplasia) to the skin, eyes and respiratory tracts and a skin sensitizer. In an oral (via gavage) OECD combined repeat dose and reproductive/developmental screening toxicity test (TG 422) in rats at doses of 10, 30, 100 mg/kg/day, squamous hyperplasia in forestomach was induced at 30 and 100 mg/kg/day. Thus, the NOAEL was 10 mg/kg/day. In many repeated inhalation studies, the changes were observed only in respiratory tract (necrosis, inflammation etc. in nasal tissues), and were likely due to irritation. The lowest NOAEL was 0.5 ppm (equivalent to 0.26 mg/kg/day) in a rabbit study. In the OECD combined study (TG 422), the NOAEL for reproductive toxicity was considered to be 30 mg/kg/day, based on a decrease in the fertility index (number of delivered animals/ number of mated animals) at 100 mg/kg. In developmental toxicity studies, teratogenic effects were not induced either by oral administration at 108 mg/kg for rats or inhalation at 291 mg/m³ for rabbits. Most <i>in vitro</i> genotoxicity studies showed positive results. In an <i>in vivo</i> micronucleus test, oral administration of glycidyl methacrylate increased the frequency of micronucleated polychromatic erythrocytes only at the highest dose (750 mg/kg in males and 1000 mg/kg in females), although mostly negative results were shown in other <i>in vivo</i> genotoxicity studies including micronucleus tests by intraperitoneal administration. Therefore, the genotoxic potential of this chemical can not be ruled out. There was no available data on carcinogenicity of this chemical.</p> | |
| Hazards to the Environment | |
| <p>Glycidyl methacrylate is readily biodegradable (OECD 301C: 100 % after 28-d) and readily hydrolyzed (T_{1/2} = 3.66 days at pH 7). This chemical has a low bioaccumulative potential judging from the low log Pow value, 0.96 at 25 °C.</p> | |

The lowest acute and chronic aquatic toxicity data reported were 14d LC₅₀ (1.9 mg/l) of fish (Medaka; *Oryzias latipes*) and 21d NOEC (1.02 mg/l) of *Daphnia magna*, respectively. An assessment factor of 100 was chosen and applied to the chronic toxicity data to determine PNEC, which is 0.01 mg/l.

Exposure

About 3,000 tones/year of glycidyl methacrylate is produced as intermediate for resins in the closed system in Japan, and ca. 3.3 tones (ca. 0.1%)/ year is released into rivers. Release to air phase is negligible. A generic fugacity model (Mackey level III) shows this chemical will be distributed mainly to water phase (99.1%) when it is discharged into water.

NATURE OF FURTHER WORK RECOMMENDED

There is a need for limiting the risk; risk reduction should be taken into account because of the high irritation, sensitization, and the genotoxic potential.

Occupational exposure information should be collected by individual member countries.

FULL SIDS SUMMARY

| CAS NO: 106-91-2 | | SPECIES | PROTOCOL | RESULTS |
|---|--|--------------------------------------|--|--|
| PHYSICAL-CHEMICAL | | | | |
| 2.1 | Melting Point | | | < -10 °C |

SIDS INITIAL ASSESSMENT REPORT

Glycidyl methacrylate (CAS No. 106-91-2)

1. IDENTITY

- OECD Name: Glycidyl methacrylate
- Synonym: 2,3-Epoxypropyl methacrylate; Glycidyl alpha-methylacrylate;
1-Propanol, 2,3-epoxy-, methacrylate
- CAS Number: 106-91-2
- Empirical Formula: C₇H₁₀O₃
- Structural Formula:

- Degree of Purity: 97.9 %
- Major Impurity: None
- Essential Additives: None
- Physical-chemical properties
 - Melting Point: < -10 °C
 - Vapour pressure: 4.2 x 10² Pa at 25 °C
 - Water solubility: Ca. 50 g/L
 - Log Pow: 0.96

2. GENERAL INFORMATION ON EXPOSURE

2.1 Production and import

The production volume of glycidyl methacrylate in Japan is 3,128 tonnes/year in 1995.

2.2 Use pattern

All of glycidyl methacrylate produced in Japan is used as monomer unit of paint resin and as intermediate of chemical products, and no consumer use is reported.

HSDB (Hazardous Substances Database) states that the chemical is a diluent in epoxy resins and a paper by Matura et al (1995) states that it is used in emulsions to impregnate paper and textile materials. It is also listed as an epoxy resin additive used in paint coating formulations and adhesive applications.

2.3 Other information

None

3. ENVIRONMENT

3.1 Environmental Exposure

3.1.1 General Discussion

Glycidyl methacrylate is readily biodegradable (OECD 301C: 100 % after 28d) and readily hydrolyzed ($T_{1/2}$ = 2.83, 3.66 and 2.22 day at pH 4,7,and 9, respectively). Direct photodegradation is not expected because glycidyl methacrylate has not absorption band in UV and VIS region.

Glycidyl methacrylate is low bioaccumulative based on Log Pow (0.96 at 25 °C).

The potential environmental distributions of glycidyl methacrylate obtained from a generic Mackay level III fugacity model is shown in Table 1. Parameters used for this model are shown as Annex to this report. The results show that, if glycidyl methacrylate is released into water or soil, it is unlikely to be distributed into other compartments. If glycidyl methacrylate is released into air, it is likely to be distributed in other compartments.

Table 1 Environmental distribution of glycidyl methacrylate
Using a generic level III fugacity model.

| Compartment | Release 100% to air | Release 100% to water | Release 100% to soil |
|-------------|------------------------|--------------------------|-------------------------|
| Air | 77.0 % | 0.4 % | 0.4 % |
| Water | 15.2 % | 99.1 % | 9.0 % |
| Soil | 7.7 % | 0.0 % | 90.6 % |
| Sediment | 0.1 % | 0.4 % | 0.0 % |

As this chemical is used in closed system as a monomer unit of paint resin or an intermediate of chemical products and is not included in consumer products, its release to the environment may occur only from the production site.

3.1.2 Predicted Environmental Concentration

As glycidyl methacrylate is produced under the well-controlled closed system, amount of release to air phase is negligibly small. The waste of glycidyl methacrylate from the production system is released to water phase after treated its own wastewater treatment plant. Therefore, Predicted Environmental Concentration (PEC) will be calculated only for the water environment.

Regional exposure

(a) According to report from a Japanese manufacturer (A), 3.3 tonnes/year (measured) of glycidyl methacrylate are released with 5.35×10^9 L/year of effluent into river. Local Predicted Environmental Concentration (PEC_{local}) is calculated to be 6.2×10^{-3} mg/L as a worst case scenario, employing the following calculation model and dilution factor of 100.

$$\frac{\text{Amount of release } (3.3 \times 10^9 \text{ mg/y})}{\text{Volume of effluent } (5.35 \times 10^9 \text{ L/y}) \times \text{Dilution Factor } (100)}$$

(b) According to report from a Japanese manufacturer (B), 1.62 tonnes/year (measured) of glycidyl methacrylate are released with 9.1×10^9 L/year of effluent into river which has flow rate of 1.82×10^{11} L/year at dry season. Local Predicted Environmental Concentration (PEC_{local}) is calculated to be 8.9×10^{-3} mg/L as a worst case scenario, employing the following calculation model and dilution factor of 20.

$$\frac{\text{Amount of release (1.62 x 10}^9 \text{ mg/y)}}{\text{Volume of effluent (9.1 x 10}^9 \text{ L/y) x Dilution Factor (20)}}$$

3.2 Effects on the Environments

3.2.1 Effects on aquatic organisms

Acute and chronic toxicity data of glycidyl methacrylate to aquatic organisms are summarized in Table 2. All tests were conducted by a GLP-laboratory. As the lowest acute and chronic toxicity data, 14d LC₅₀ of *O. latipes* and 21 d NOEC (reproduction) of *D. magna* were selected, respectively (Table 2). An assessment factor of 100 was chosen and applied to the chronic toxicity data to determine PNEC, because chronic toxicity data for fish were not available. Thus, PNEC of glycidyl methacrylate is 0.01 mg/l.

Table 2. Acute and chronic toxicity data of glycidyl methacrylate to aquatic organisms at different trophic levels.

| Species | Endpoint | Conc. (mg/l) | Remarks |
|--|--------------|--------------|----------|
| <i>Selenastrum capricornutum</i> (algae) | Bms 72h EC50 | 14.6 | a, 1) |

3.2.2 Terrestrial effects

No data available

3.2.3 Other effects

No data available

3.3 Initial Assessment for the Environment

Glycidyl methacrylate is readily biodegradable and readily hydrolyzed. This chemical seems to have a low bioaccumulation potential judging from a low log P_{ow} value. The lowest acute toxicity

value was 1.9 mg/l (14d LC₅₀ of fish Medaka; *O. latipes*) and 1.0 mg/l (21 d NOEC of *D. magna*), respectively.

4. HUMAN HEALTH

4.1 Human Exposure

4.1.1 Occupational exposure

Glycidyl methacrylate is produced in closed systems and used for resin synthesis. The occupational exposures are expected through inhalation and dermal route. The atmospheric concentration was measured at two production sites. The average concentrations, working schedules and EHEs for each operation were shown in the Table. Dermal exposure was also calculated, based on EASE model. The duration of dermal exposure was assumed to be 5 minutes. If a single worker (body weight; 70 kg, respiratory volume; 1.25 m³/hr) is assigned to implement all daily operation without protection, the highest daily intake (combined EHE) is calculated as 0.22 mg/kg/day as the worst case. Practically, workers always wear protective gloves and respiratory protective equipment (mask) during the operation.

| | Frequency Times/day | Duration hr | Working hr/day | Average Concentration mg/m ³ | Average EHE mg/kg/day | Combined EHE mg/kg/day |

* Dermal exposure; mg/cm²/day

EHE: Estimated Human Exposure

<: Concentrations were below determination limit. Figure is lower determination limit used for EHE calculation.

The data shown were essentially personal monitoring data. Two air samplers were kept on both sides of the operator's face approximately 20 cm away.

Analytical method:

Sampling: XAD2 tube, Air flow rate: 1 liter/min, Air volume: 3 liter

Desorption: Butyl acetate

Determination: Gas chromatograph with FID

Date of Sampling: October 1998

Activity of operator:

Sampling: Take ca. 100 ml of GM from the sampling nozzle in a glass bottle, just like taking water from faucet.

Maintenance: Replace a strainer to trap polymeric by-products with a new one. The strainer housing was isolated from the flow line, but the housing was filled with glycidyl methacrylate during this operation.

Can filling: Filling 18-liter cans using semi-automatic instrument. Operator removed the cap of the can, and placed the can under the nozzle after filling replace the cap. Filled can was transferred by a conveyer.

Analysis: Analyze the quality control sample with GC.

Operator takes a neat sample by a micro-syringe from the bottle in a hood, and injects it to GC.

Sludge removal: Remove residue of distillation vessel manually after residual glycidyl methacrylate was removed by vacuum.

In following operation, operator did not handle glycidyl methacrylate directly.

Transfer: Transfer the product to storage tank using pump.

Waste treatment: The crude product is washed with water to remove sodium chloride.

Waste water is transferred to treatment plant.

4.1.2 Consumer exposure

Glycidyl methacrylate produced in Japan is used as monomer unit of paint resin and as intermediate of chemical products. As the detailed information could not be given in Japan, one report indicates it is used as paints in the product concentrations of 1 to 5 % and the other shows it is mainly used as car coating paints in car industry. Therefore consumer exposure might be low.

4.1.3 Indirect exposure via the environment

Although glycidyl methacrylate is readily biodegradable and low bioaccumulative, the exposure to the general population via the environment would be possible through drinking water processed from surface water and through fish which may accumulate this chemical.

The concentration in drinking water should be estimated to be equal to PEC calculated in Section 3.1, i.e. 8.9×10^{-3} mg/l. The daily intake through drinking water is calculated as 2.97×10^{-4} mg/kg/day (2 l/day, 60 kg b.w.).

Using the bioconcentration factor of 1.0 estimated from logPow (0.96), the concentration of this chemical in fish can be calculated as follows:

$$PEC_{\text{fish}} = (8.9 \times 10^{-3} \text{ mg/l}) \times 1.0 = 8.90 \times 10^{-6} \text{ mg/g-wet}$$

As a daily intake of fish in Japan is estimated to be 90 g for 60 kg body weight person, a daily intake of this chemical will be 1.34×10^{-5} mg/kg/day.

4.2 Effects on Human Health

a) Motion of action of the chemical, toxicokinetics and metabolism

Toxicokinetics of glycidyl methacrylate were investigated in rabbits. After an intravenous injection at 200 mg/kg, over 95 % of the parent compound disappeared from the blood within 10 minutes according to two-compartment open model. Following a subcutaneous injection at 800 mg/kg, the toxicokinetics appeared to fit a first-order absorption one-compartment open model. This chemical was metabolized by incubation with whole blood, plasma, erythrocyte suspension, and homogenates of various tissues. The subcutaneous co-administration of tri-*o*-cresyl-phosphate (a carboxylesterase inhibitor) with this chemical resulted in about a ten-fold increase in the maximum blood concentrations, compared to those of animals dosed with this chemical alone. (Shi Tao *et al.*: 1988)

The metabolism of glycidyl methacrylate in mammals will likely proceed by at least two different and competing enzyme systems, epoxide hydratase and non-specific carboxylesterases. Species differences in the activity of these enzymes suggest that the carboxylesterase route of metabolism may predominate in the nasal tissue of rabbits (yielding glycidol and methacrylic acid) whereas the epoxide hydratase route would likely predominate in rats and humans (producing glycerol methacrylate, then glycerol and methacrylic acid by carboxylesterase). (Bogdanffy *et al.*: 1987, Dahl *et al.*: 1987, Glatt *et al.*: 1984, Mattes and Mattes: 1992, Pacifici *et al.*: 1981)

b) Acute toxicity

[SIDS data] Oral LD₅₀ value for glycidyl methacrylate was 597 mg/kg b.w. for rat (Zdravko *et al.*: 1985). In inhalation toxicity study by OECD TG 403, there was no mortality observed in rats exposed for 4 hours at 2,394 mg/m³, the highest practically attainable vapor concentration. Change of respiration (labored breathing) and eyes (irritation and corneal opacity), and decrease in body weight were induced even at the lowest concentration of 1,563 mg/m³. (Nitschke *et al.*: 1990) Dermal LD₅₀ for rabbits was 480 mg/kg b.w. (Smyth *et al.*: 1969).

In another inhalation toxicity study, acute exposure to rats with saturated vapour of this chemical resulted in a maximum survival time of 2 hours (Smyth *et al.*: 1969). It was reported that saturated vapour of glycidyl methacrylate at 20 °C was 474 ppm (2,754 mg/m³) (Draft Workplace Environmental Exposure Level Guide: 1999).

| Routes | Strain | Type | Values | Reference |
|------------|---------------|------------------|------------------------------|---|
| Oral | Rats | LD ₅₀ | 597 mg/kg | Zdravko <i>et al.</i> : 1985 |
| | Rats | LD ₅₀ | about 700 mg/kg | Olson: 1960 Smyth <i>et al.</i> : 1969 |
| | Rats* | LD ₅₀ | 451 mg/kg | EPA/OTS: 1992 |
| | Mice | LD ₅₀ | 390 mg/kg | Zdravko <i>et al.</i> : 1985 |
| | Mice | LD ₅₀ | 1,050 mg/kg | Smyth <i>et al.</i> : 1969 |
| | Guinea pigs | LD ₅₀ | 697 mg/kg | Zdravko <i>et al.</i> : 1985 |
| Inhalation | Rats | LC ₀ | 2,394 mg/m ³ /4hr | Nitschke <i>et al.</i> : 1990 |
| | Rats** | LCL ₀ | 1,400 mg/m ³ /6hr | Haag: 1953 |
| | Rabbits** | LCL ₀ | 1,400 mg/m ³ /6hr | Haag: 1953 |
| | Guinea pigs** | LCL ₀ | 1,400 mg/m ³ /6hr | Haag: 1953 |

* as a mixture of glycidyl methacrylate (97.8 %), epichlorohydrin (0.3 %) and dichlorohydrin (0.6 %)

** Changes in lungs, thorax, respiration, *etc.* were observed.

c) Irritation

Skin irritation

Glycidyl methacrylate induced high irritation to the skin of rabbits (Ou-Yang *et al.*: 1988). The 0.1 ml applied area showed red, swelled and blistered after one or two days, subdermal bleeding and ulcers after three days, and hard, thicker, cracked, pigmentation after five days. The pathological changes were degeneration and necrosis of surface skin cells, disappearance of cellular boundaries, displaying pink staining material, bleeding in the corium cells and lymph cell infiltration with accompanying formation of abscesses.

There were other data on skin irritation of glycidyl methacrylate. A single covered topical application to the skin of albino rabbits for four hours induced moderate to severe skin irritation including necrosis with slight to moderate edema (Olson: 1960). A 10% solution (aqueous) produced slight redness and edema after 1 application (for 4 hours) and a moderate burn after 2 applications (Olson: 1960). In DOT standard test (equivalent to OECD Test Guideline 404), corrosiveness occurred by 4 hours exposure but not 1-hour exposure (Lockwood: 1991). However, there was no more information on these studies.

Eye irritation

Direct instillation of undiluted glycidyl methacrylate to the eye of albino rabbits induced moderate to severe irritation and corneal damage. Corneal damage did not heal within 7 days post-dosing. This ocular damage was prevented by washing with water within 30 seconds. (Olson: 1960, Smyth: 1969)

In inhalation study using rats, eye irritation was also induced. Acute exposure for 4 hours induced eye irritation at 1,563 mg/m³ and 2,394 mg/m³. Corneal opacity was also observed slightly at 610 mg/m³, and moderately at 1,563 mg/m³ and 2,394 mg/m³. These changes did not heal within 14 days post-exposure. (Nitschke *et al.*: 1990) In subacute study, rats were exposed at 58.2, 223 and 931 mg/m³, 6 hours/day, 5 days/week for 2 weeks. As a result, eye irritation and corneal clouding were observed at 931 mg/m³. (Landry *et al.*: 1991)

Respiratory irritation

Labored breathing was induced in rat by acute inhalation exposure for 4 hours at 1,563 mg/m³ and 2,394 mg/m³ (Nitschke *et al.*: 1990). In another acute inhalation study, changes in lungs, thorax, respiration, *etc.* were observed in rats, rabbits, guinea pigs and dogs. In this study, exposure was conducted at 1,400 mg/m³ for 6 hours (Haag: 1953). These changes may be resulted from respiratory irritation of this chemical.

In inhalation repeated dose toxicity studies, there were also many changes in respiratory tract, such as noisy and difficult respiration (mouth breathing), and hyperplasia, necrosis and inflammation in nasal tissues. In one subacute toxicity study, rabbits were exposed at 2.9, 12, 29 or 60 mg/m³ 6 hours/day, daily for 13 consecutive days. Treatment-related degeneration of the nasal olfactory epithelium was observed at 12 mg/m³. At 29 and 60 mg/m³, there were olfactory epithelial degeneration, and the hyperplasia, erosions, ulcers and inflammation of the nasal epithelium. After

4-week recovery period, there was complete reversibility of these changes except for olfactory epithelial degeneration observed at 29 and 60 mg/m³, which showed only partial reversibility. At 12 mg/m³, nasal tissue was indistinguishable from controls at one month post-exposure. (Cieszlak *et al.*, 1996)

In European labelling and classification, this chemical is listed as R36/38, irritating to eyes and skin.

Based on these data, it is considered that glycidyl methacrylate irritates to the skin, eyes and respiratory tract. The irritation of this chemical is likely strong.

d) Sensitisation

Guinea pigs received three topical applications with 0.4 ml of 10 or 25 % glycidyl methacrylate in dipropylene glycol monomethyl ether during the three-week induction phase. The single challenge application induced slight erythema in these animals (7/10). (The Dow Chemical Company: 1992)

Ou-Yang *et al.* (1988) reported on delayed and rapid allergy reaction tests in guinea pigs. In delayed allergy reaction test, localized smear applications or intradermal injection with 0.1 ml of 1 % glycidyl methacrylate in acetone induced hyperemia, edema, scleroma and necrosis. Those changes belong to the strong allergenic category. As for rapid allergic reaction test, two tests by active and passive stimulation were conducted. In the active stimulation, 0.5 % glycidyl methacrylate with homologous serum albumin was injected intradermally and the challenge was conducted intravenously. Breathing difficulties, wheezing, increased mouth and nose secretions, spasms and death were observed, belonging to the strong allergic category. In the passive stimulation, firstly, the diluted serum given from the sensitized guinea pig was injected subcutaneously to other animals and one hour later, 0.5 ml of 0.1 % glycidyl methacrylate with homologous serum albumin was injected intravenously to the same animals. Blue circles or spots observed belonged to the strong allergic category. Both the delayed and rapid allergy test results showed that glycidyl methacrylate was a strong sensitizer. The author reported that this might be the reason that the epoxy radical of glycidyl methacrylate easily combined with protein.

There were two data on human patch test.

Three cases of allergic contact hypersensitivity to glycidyl methacrylate used in adhesive sealant manufacturing were reported. Both closed and open patch testing with 1 % glycidyl methacrylate solution in petrolatum was positive in all 3 cases. Symptoms included erythema, edema, and vesiculation and a strong 2+ reaction as scored according to the International Contact Dermatitis Research Group classification. (Dempsey: 1982)

Patch test was conducted for a 31-year-old non-atopic woman, who had worked as a chemist and mixed emulsions used to impregnate paper and textile materials to make them oil and water resistant. In this work, she had been in contact with acrylate derivatives (glycidyl methacrylate, ethoxyethyl acrylate, etc.). In relation to this work, she had a history of recurrent acute vesiculopapular hand dermatitis with severe itching and burning mainly on the fingertips, palmar and dorsal aspects of the fingers, and both palms. As a result of patch test, she reacted only to nickel, glycidyl methacrylate (0.01 and 0.05 % acet.) and ethoxyethyl acrylate among the European standard series and (meth) acrylate series. This reaction to nickel was relevant to her jewelry intolerance. (Matura *et al.*: 1995)

In European labelling and classification, this chemical is classified as R43, may cause sensitisation by skin contact

Based on these data, glycidyl methacrylate is considered to be a skin sensitizer.

e) Repeated toxicity

[SIDS data] Oral toxicity study of glycidyl methacrylate was performed in SD (Crj: CD) rats by an OECD combined repeated dose and reproductive/developmental toxicity screening test (OECD TG 422). Administration was conducted at doses of 10, 30 and 100 mg/kg/day by gavage for 45 days in males and from 14 days before mating to day 3 of lactation in females. (MHW, Japan: 1997)

Salivation was observed at 30 mg/kg (5/12) and 100 mg/kg (12/12) in males. In males, there was an increase in absolute and relative kidney and adrenal weights at 100 mg/kg. In blood chemistry of males, increase in total protein and albumin was observed. These changes were not considered as adverse effects. In histological examination, squamous hyperplasia in forestomach was observed at 30 and 100 mg/kg in males and cellular infiltration in forestomach at 100 mg/kg in females. These histological changes were considered to be due to the irritation of glycidyl methacrylate. NOAEL for oral repeat toxicity was considered to be 10 mg/kg/day for males and 30 mg/kg/day for females.

Two other orally repeated toxicity studies were reported.

One-year study is very limited (Hadidian *et al.*, 1968). Rats (3 males and 3 female) were dosed 5 days/week by gavage at 0.1 mg/kg. Groups of 15 male and 15 female rats were also dosed at 0.3 mg/kg. The authors concluded that no tissue effects related to the treatment were found. These dosages are considered to be too low.

In another study, five male and female rabbits were given orally at 50 mg/kg daily for 15 days (Ou-Yang *et al.*: 1988). Some animals showed slow reactions, head shaking and prostration, and two animals died. There were several hematological and pathological changes including bleeding, necrosis and so on in heart, liver, kidneys and stomach.

This study can not be adapted to hazard assessment because of unreliability such as no Test Guideline, no GLP, only single dose and unlikely severe systemic toxicity compared to other reliable oral and inhalation toxicity studies using rats and rabbits, and insufficient information on protocol and data analysis including purity of chemical and pathological data.

Subacute inhalation toxicity studies were performed in rats and rabbits.

Rats were exposed to glycidyl methacrylate at concentrations of 58.2, 233 or 931 mg/m³ for 2 weeks (6 hours/day, 5 days/week) (Landry *et al.*: 1991). These three concentrations were calculated as 7.09, 28.4 or 113 mg/kg/day. Decrease in body weight was observed at 233 and 931 mg/m³. At 931 mg/m³, general debilitation with noisy and difficult respiration (mouth breathing), eye irritation, corneal clouding and distended abdomen (day 4) were observed. The animals at 931 mg/m³ were terminated early on day 4 because of the severity of the respiratory and ocular effects. Microscopically, there was severe multifocal necrosis and inflammation of the olfactory epithelium in the nasal cavity. At 233 mg/m³, there were slight to moderate multifocal necrosis, and inflammation of the respiratory and olfactory nasal epithelium. At 58.2 mg/m³, microscopically there was very slight multifocal necrosis of individual respiratory epithelial cells in 3 of 5 males and in 2 of 5 females. These changes in respiratory tract were considered due to irritation of glycidyl methacrylate. There were no histopathological changes in any other tissues. Therefore, 58.2 mg/m³ (7.09 mg/kg/day) was considered to be LOAEL because of tissue damages in respiratory tract.

Rabbits were exposed at 2.91, 11.6, 29.1, 58.2 mg/m³ 6 hours/day, daily for 13 consecutive days. (Cieszlak *et al.*, 1996) Treatment-related degeneration of the nasal olfactory epithelium was observed at 11.6 mg/m³. At 29.1 and 58.2 mg/m³, there were olfactory epithelial degeneration, and the hyperplasia, erosions, ulcers and inflammation of the nasal epithelium. After 4-week recovery period, there was complete reversibility of these changes except for olfactory epithelial degeneration observed at 29.1 and 58.2 mg/m³, which showed only partial reversibility. At 11.6 mg/m³, nasal tissue was indistinguishable from controls at one month post-exposure. 2.91 mg/m³ (0.26 mg/kg/day) was considered to be NOAEL. Unfortunately purity of chemical and GLP were not mentioned.

Subchronic inhalation toxicity study was conducted in rats at concentrations of 2.9, 12 or 87 mg/m³ for 13 weeks (6 hours/day, 5 days/week) (Landry *et al.*: 1996). These three doses were calculated as approximately 0.35, 1.46 or 10.6 mg/kg/day, respectively. There were no treatment related in-life observations, and no significant treatment-related effects on body weight, urinalysis, clinical chemistry or hematology parameters, as well as gross pathologic changes or organ weights at any exposure level. Treatment-related effects were limited to hyperplasia of respiratory epithelium of the nasal tissues in all animals at 87 mg/m³. In all affected animals, the hyperplastic respiratory epithelium was approximately two to three times as thick as in control animals, and was located in the anterior portions of the nasal passages, involving the tips of the turbinates and the lateral walls of the nasal passages. These changes were considered to be resulted from reparatory irritation. Therefore, NOAEL was considered 12 mg/m³ (1.46 mg/kg/day) for both sexes.

There was 26 weeks inhalation toxicity study at concentrations of 15.3 and 206 mg/m³ in rats and rabbits (Ouyang Guoshun *et al.*: 1990). A wide range of toxic effects, such as lesion in central nervous system, cardiovascular system, liver and kidney, were observed in both species at the low and high doses. However, because of the higher vapor pressure and lower purity, the author suggested that the test material used in this study contained components other than glycidyl methacrylate, which may have contributed to the toxicity observed. Therefore these systemic toxicities observed in the studies are questionable.

Based on all above information, the major toxicity was tissue damages in the first exposure sites such as forestomach by oral administration and respiratory tract by inhalation, due to the irritation of chemical and NOAELs were 10 mg/kg for rat oral, 12 mg/m³ for rat inhalation and 2.91 mg/m³ for rabbit inhalation.

f) Reproductive/developmental toxicity

Reproductive toxicity

[SIDS data] Oral toxicity study was performed in SD (Crj: CD) rats by an OECD combined repeated dose and reproductive/developmental toxicity screening test (OECD TG 422). Administration was conducted by gavage at doses of 10, 30 and 100 mg/kg/day from 14 days before mating to 14 days after mating in males and from 14 days before mating to day 3 of lactation in females. (MHW, Japan: 1997)

The fertility index (number of delivered animals/ number of mated animals) decreased significantly at 100 mg/kg. There were no effects on the estrous cycle, copulation index, or gestation length. No significant changes in the numbers of corpora lutea, implants, pups born and live pups as well as the implantation and delivery indices were observed. There were no significant differences in the gestation index, live birth index or viability index on day 4. Histopathological analysis of the gonads showed no significant effect considered to cause infertility in all treatment groups. No change in the number of gonocyte per Sertoli cell was observed in epithelium of seminiferous

tubule (stage VIII) of all survival males at 100 mg/kg. No abnormalities attributable to the administration of this chemical were noted in the body weights of live pups or on necropsy of pups in any treated group. Therefore, NOAELs for reproductive performance of parents and pup development were considered to be 30 mg/kg/day and 100 mg/kg/day, respectively.

Male mice injected i.p. with 5 consecutive daily doses of 0, 25, 50 or 100 mg/kg/day showed an increase in the percentage of abnormal sperm and decrease in the number of sperm (Xie *et al.*: 1990). These results were confirmed in a subsequent study where mice were dosed i.p. with 0, 5, 25 or 100 mg/kg for five consecutive days (Vedula *et al.*, 1994). At 100 mg/kg, mice had decreased caudal epididymal weights, slightly lower testicular weights, decreased sperm counts and increased abnormal sperm. Mice given 25 mg/kg/day showed decreased sperm counts and increased abnormal sperm. These results might support the decreased fertility index of rat study at 100 mg/kg/day.

Developmental toxicity

Glycidyl methacrylate was administered by gavage to rats during day 5 to day 15 of gestation at doses of 5.38, 10.76, 21.52 and 108.0 mg/kg/day. The animals were sacrificed on day 19 of pregnancy. (OuYang *et al.*: 1988)

As maternal toxicity, there was significant decrease in body weight gain at 108.0 mg/kg. There was a statistically significant increase in the fetal resorption rate at the 108.0 mg/kg. The percentage of pups stillborn was somewhat higher than control at all dose levels. However, because this change was not dose-dependent and statistically significant change was only at 10.76 mg/kg, this was not considered to be chemical-related change. Neither birth defects nor fetal abnormalities were noted in rats treated with this chemical. There was also no significant difference in fetal body weight from the control. Therefore, NOAELs were considered to be 21.52 mg/kg/day for maternal toxicity and 108.0 mg/kg/day for teratogenicity.

There were two inhalation tests on developmental toxicity.

Rabbits were exposed to glycidyl methacrylate at concentrations of 29.1, 58.2 and 291 mg/m³, 6 hours/day, daily during day 7 to day 19 of gestation (Vedula *et al.*: 1995). Daily intake is calculated as 2.62, 5.24 and 26.2 mg/kg/day. Respiratory distress and decrease in feed consumption was observed at 291 mg/m³. Less severe signs of ocular and respiratory irritation consisting of reddened eyes, wet muzzle and sneezing after exposure were observed at 58.2 mg/m³. Treatment-related histopathologic alterations of the nasal tissues (hyperplasia, necrosis, etc.) were present in all animals treated with this chemical. Because of respiratory distress, animals at 291 mg/m³ were removed early from study after the third exposure. Therefore, evaluation of reproductive and embryonal/fetal parameter was precluded. There was no adverse effect on any reproductive and embryo/fetal parameter at 29.1 and 58.2 mg/m³. LOAEL for maternal toxicity was 29.1 mg/m³ (2.62 mg/kg/day) and NOAEL for teratogenicity was 58.2 mg/m³ (5.24 mg/kg/day).

Rabbits were also exposed to glycidyl methacrylate at concentrations of 2.91, 11.6 and 58.2 mg/m³, 7 hours/day, daily during day 7 to day 19 of gestation (Vedula *et al.*: 1995). Daily intake is calculated as 0.31, 1.22, 6.11 mg/kg/day. The principal indication of maternal toxicity was inflammation of the nasal olfactory and respiratory epithelium at the 11.6 and 58.2 mg/m³. There was no adverse effect on any reproductive and embryo/fetal parameter at any doses. Therefore, NOAEL for maternal toxicity was 2.91 mg/m³ (0.31 mg/kg/day) and NOAEL for teratogenicity was 58.2 mg/m³ (6.11 mg/kg/day).

As three reliable developmental studies by two different routes, oral and inhalation, indicated no teratogenicity even at the highest doses which showed the maternal toxicity, glycidyl methacrylate is not considered to have developmental toxicity.

g) Genetic toxicity

Bacterial test

[SIDS data] Glycidyl methacrylate was mutagenic to *Salmonella typhimurium* TA97, TA100, TA1535 with and without metabolic activation but not to TA98 (Dorothy *et al.*: 1986, The Goodyear Tire & Rubber Company: 1981, OuYang *et al.*: 1988).

Glycidyl methacrylate was mutagenic to *Klebsiella pneumoniae* without metabolic activation (Voogd *et al.*: 1981). In *Escherichia coli*, this chemical induced SOS repair with and without metabolic activation (von der Hude *et al.*: 1990). This chemical was shown to react with the DNA of the gene governing tetracycline resistance in the plasmid pBR322. The modified DNA was transferred to a receptor cell (*Escherichia coli* HB 101) to screen for mutations based on alterations in phenotypic changes. Results showed the mutations caused by reactions of glycidyl methacrylate with the plasmid were stable and heritable (Xie *et al.*: 1990a).

Non-bacterial test *in vitro*

[SIDS data] In chromosomal aberration test of glycidyl methacrylate, using cultured Chinese hamster lung (CHL/IU) cells, both structural abnormality and polyploidy were induced with and without metabolic activation. However, a trend test showed no dose-dependency for the induction of polyploidy with the 24 hours continuous treatment and the short-term treatment with the metabolic activation system. (MHW, Japan: 1997)

In cell cultures, glycidyl methacrylate induced hypoxanthine-guanine-phosphoribosyl transferase forward gene mutation with metabolic activation in Chinese hamster ovary cell (Linscombe and Engle: 1995), very slight increase of unscheduled DNA synthesis in lymphocytes of human and/or rat (Xie *et al.*: 1990b), non-reverse type inhibition of the DNA replication in lymphocytes of human and/or rat (Xie *et al.*: 1989), sister-chromatid exchange without metabolic activation in Chinese hamster V79 cells (von der Hude *et al.*: 1991), transformation of Syrian hamster embryonic cells (SHE) (Xie *et al.*, 1992) and transformation in diploid golden Syrian hamster embryo (SHE) cells (Yang *et al.*; 1996). This chemical was strongly and covalently bound with calf thymus DNA *in vitro* (Xie *et al.*: 1990b).

in vivo test

[SIDS data] In micronucleus assay, mice was administered by gavage with glycidyl methacrylate at a single dose of 188, 375 and 750 mg/kg in males and 250, 500 and 1000 mg/kg in females. The frequency of micronucleated polychromatic erythrocytes in both sexes was significantly increased only at the highest doses 48 hour after administration. (MHW, Japan: 1997)

There were many data on the *in vivo* genotoxic potential of glycidyl methacrylate. Three of them were mouse bone marrow micronucleus tests by intraperitoneal administration. In one study, this chemical produced an increase in the number of cells with micronuclei at doses of 25, 50 and 100 mg/kg, although the increase was very slight and showed an inversed dose-response (Ou-Yang *et al.*, 1988). On the other hands, this chemical did not cause an increase in the number of cells containing micronuclei in two other studies with doses of 75, 150, and 300 mg/kg (Lick *et al.*, 1995) or doses of 42.2, 133, 422, and 464 mg/kg (INBIFO: 1979).

This chemical increased unscheduled DNA synthesis in germ cell of male mice but this effect was very slight and not dose-related (Xie *et al.*: 1990b). In inhalation gene mutation assay using transgenic Big Blue® Fischer 344 rats with the *lacI* locus, there were no statistically significant increases in the frequencies of *lacI* mutants in either the olfactory or respiratory epithelium at 145.5 mg/cm³ (17.7 mg/kg/day) (No reference in Draft Workplace Environmental Exposure Level Guide (1999))

Most genotoxicity studies *in vitro* showed positive results. In micronucleus test *in vivo*, oral administration increased the frequency of micronucleated polychromatic erythrocytes at the highest dose, although mostly negative results were shown in other *in vivo* genotoxicity studies including micronucleus tests by intraperitoneal administration. Therefore, genotoxic potential of this chemical can not be ruled out.

g) Carcinogenicity

There was no available data.

h) Any other human health related information that is available

1: Specific toxicities

Neurotoxicity

Fischer 344 rats were exposed by inhalation to glycidyl methacrylate at approximately 0.5, 2 or 15 ppm (2.9, 12, 87 mg/m³), 6 hours/day, 5 days/ week for 13 weeks (calculated daily dose: 0.35, 1.46, 10.59 mg/kg/day). At week 4, there was a low incidence of rat with nasal discharge and enlarged nostrils at 2 and 15 ppm. There were no other treatment-related effects. A functional observation battery (FOB) and motor activity (MA) were conducted preexposure and at the end of each month of exposure. In addition, the postexposure neurotoxicity evaluation focused on evoked potential testing of the visual (FEP), auditory (ABR), somatosensory system (SEP), and caudal nerves (CNAP), and a comprehensive neuropathological examination. There was no evidence of neurotoxic effects at any exposure level. (Mattsson *et al.*: 1996)

2: Experience with human exposure

Two human patch test data and the evaluation are given at section d).

4.3 Initial Assessment for Human Health

Glycidyl methacrylate is produced in closed systems and used for resin synthesis. The occupational exposures are expected through inhalation and dermal route. Consumer exposure might be low because of no consumer use. Environmental exposure also might be low because of ready biodegradation and low bioaccumulation. Acute toxicity of glycidyl methacrylate is low via the oral administration or inhalation route. This chemical is considered both highly irritating to the skin, eyes and respiratory tracts and a skin sensitizer. In an oral repeat dose study, squamous hyperplasia in forestomach was induced at 30 and 100 mg/kg/day. In repeated inhalation study, necrosis and inflammation in nasal tissues were observed. The reproductive toxicity was only a decrease in the fertility index (number of delivered animals/ number of mated animals) at 100 mg/kg. In developmental toxicity study, teratogenic effects were not induced either by oral administration or inhalation route. Most *in vitro* genotoxicity studies showed positive results. In an *in vivo* micronucleus test, oral administration increased the frequency of micronucleated polychromatic erythrocytes at the highest dose, although mostly negative results were shown in other *in vivo*

genotoxicity studies including micronucleus tests by intraperitoneal administration. Therefore, genotoxic potential of this chemical can not be ruled out. Although there was no available data on carcinogenicity of this chemical, carcinogenic potential in nasal cavity is highly expected because whole toxicity profile of glycidyl methacrylate is very similar to that of formaldehyde (WHO/IARC: 1995).

5. CONCLUSIONS AND RECOMMENDATIONS

5.1 Conclusions

Exposure

About 3,000 tones/year of glycidyl methacrylate is produced and used as intermediate for resins in the closed system in Japan, and ca. 3.3 tones (ca. 0.1%)/ year is released into rivers. Release to air phase is negligible. A generic fugacity model (Mackey level III) shows this chemical will be distributed mainly to water phase (99.1%) when it is discharged into water.

Hazards to the Environment

Glycidyl methacrylate is readily biodegradable (OECD 301C: 100 % after 28-d) and readily hydrolyzed ($T_{1/2} = 3.66$ days at pH 7). This chemical has a low bioaccumulative potential judging from the low log Pow value, 0.96 at 25 °C. The lowest acute and chronic aquatic toxicity data reported were 14d LC₅₀ (1.9 mg/l) of fish (Medaka; *Oryzias latipes*) and 21d NOEC (1.02 mg/l) of *Daphnia magna*, respectively. An assessment factor of 100 was chosen and applied to the chronic toxicity data to determine PNEC, which is 0.01 mg/l.

Human Health Hazards

Acute lethal toxicity of glycidyl methacrylate is low via the oral administration route. No mortality was observed in rats following inhalation exposure up to 2,394 mg/m³, the highest practically attainable vapor concentration. This chemical is considered both highly irritating (including necrosis, degeneration and hyperplasia) to the skin, eyes and respiratory tracts and a skin sensitizer. In an oral (via gavage) OECD combined repeat dose and reproductive/ developmental screening toxicity test (TG 422) in rats at doses of 10, 30, 100 mg/kg/day, squamous hyperplasia in forestomach was induced at 30 and 100 mg/kg/day. Thus, the NOAEL was 10 mg/kg/day. In many repeated inhalation studies, the changes were observed only in respiratory tract (necrosis, inflammation etc. in nasal tissues), and were likely due to irritation. The lowest NOAEL was 0.5 ppm (equivalent to 0.26 mg/kg/day) in a rabbit study. In the OECD combined study (TG 422), the NOAEL for reproductive toxicity was considered to be 30 mg/kg/day, based on a decrease in the fertility index (number of delivered animals/ number of mated animals) at 100 mg/kg. In developmental toxicity studies, teratogenic effects were not induced either by oral administration at 108 mg/kg for rats or inhalation at 291 mg/m³ for rabbits. Most *in vitro* genotoxicity studies showed positive results. In an *in vivo* micronucleus test, oral administration of glycidyl methacrylate increased the frequency of micronucleated polychromatic erythrocytes only at the highest dose (750 mg/kg in males and 1000 mg/kg in females), although mostly negative results were shown in other *in vivo* genotoxicity studies including micronucleus tests by intraperitoneal administration. Therefore, the genotoxic potential of this chemical can not be ruled out. There was no available data on carcinogenicity of this chemical.

5.2 Recommendations

Human health

There is a need for limiting the risk; risk reduction should be taken into account because of the high irritation, sensitization, and the genotoxic potential.

Occupational exposure information should be collected by individual member countries.

Appendix 1

Method for Prediction of Environmental Concentration of Pollutant in Surface Water

1. Predicted environmental concentration in the local environment (PEC_{local}) with effluent release into river

When decomposition, precipitation and vaporization of pollutant can be ignored, it is used that simplified equation by complete mixing model shown with equation (1) to calculate predicted environmental concentration in the local environment (PEC_{local}) as for release effluent into river.

$$\text{PEC}_{\text{local}} \text{ (mg/L)} = \frac{C_o Q + C_s Q_s}{Q + Q_s} \quad (1)$$

Where

C_o: Concentration of pollutant in upper stream of release point (mg/L)

C_s: Concentration of pollutant in effluent (mg/L)

Q: Flow rate of river (m³/day)

Q_s: Flow rate of effluent released into river (m³/ day)

At the equation (1), when C_o can be considered as 0, dilution factor of pollutant in the river (R) can be shown with following equation.

$$R = C_s/C = (Q + Q_s) / Q_s \quad (2)$$

As the worst case, it is used to employ a flow rate at dry season as flow rate of river (Q). When flow rate at dry season is indistinct, it is estimated using the following equation in Japan.

$$\text{Flow rate at dry season} = \text{mean flow late} / 2.5 \quad (3)$$

2. Predicted environmental concentration in the local environment (PEC_{local}) with effluent release into sea

For prediction of concentration of pollutant in the sea water with effluent, it is employed generally Joseph-Sendner's equation (4). This equation is one of analytic solution led under the following conditions from diffusion equation.

- 1 It is adopted large area of sea or lake.
- 2 The flow rate of effluent and concentration of pollutant in the effluent are constant, and distribution of concentration is able to regard as equilibrium state.
- 3 Effluent is distributed uniformly to vertical direction, and it spreads in a semicircle or segment to horizontal direction.
- 4 Diffusion coefficient of pollutant at the sea is in proportion to distance from release point of effluent.
- 5 There is not any effect of tidal current.
- 6 Decomposition of pollutant can be ignored.

$$C(x) = (C_s - C(r)) \left(1 - \exp \left(- \frac{Q_s}{\theta d p} \left(\frac{1}{x} - \frac{1}{r} \right) \right) \right) + C(r) \quad (4)$$

Where

C(x): Concentration of pollutant at distance x (m) from release point

C_s: Concentration of pollutant in effluent

C(r): Concentration of pollutant at distance r (m) from release point

Q_s: Flow rate of effluent (m³/day)

θ: Opening angle of seacoast (rad.)

d: Thickness of diffusion layer (m)

P: Diffusion velocity (m/day) (1.0 ± 0.5 cm/sec)

When C(x) is 0 at r = ∞ and density stratification is ignored for simplification, Joseph-Sendner's equation (4) is simplified to equation (5)

$$C(x) = C_s \left(1 - \exp \left(- \frac{Q_s}{\theta d p x} \right) \right) \quad (5)$$

Because of $Q_s/\theta d p x \ll 1$ except vicinity of release point, dilution factor in distance x from release point R(x) can be shown with equation (6).

$$R(x) = C_s/C(x) = \theta d p x/Q_s \quad (6)$$

When it is employed following parameters in equation (6) as default, dilution factor R can be shown with equation (7).

P = 1 cm/sec (860 m/day)

θ = 3.14

d = 10 m

x = 1000 m

$$R = 2.7 \times 10^7/Q_s \quad (7)$$

Q_s: volume of effluent (m³/day)

Appendix 2

Sample of Risk Assessment for Environment and Human Health in Japan

1. Initial Risk Assessment for the Environment

PNEC of this chemical was calculated as 0.01 mg/l. PECs from the Japanese local exposure scenario, case A and case B, were calculated to be 6.2×10^{-3} and 8.9×10^{-3} mg/l, respectively.

Thus

$$PEC_{\text{local}} (\text{case A} / \text{PNEC} = (6.2 \times 10^{-3}) / 0.01 = 0.62 < 1$$

$$PEC_{\text{local}} (\text{case B} / \text{PNEC} = (8.9 \times 10^{-3}) / 0.01 = 0.89 < 1$$

PEC is close to PNEC.

2. Initial Risk Assessment for the Human Health

Occupational exposure

Glycidyl methacrylate is produced in a closed system at industries and workers wear protective gloves and respiratory protective equipment (mask) during the operation. The occupational exposures are expected through inhalation and skin in limited workers. The atmospheric concentration was measured at two production sites in Japan. Based on these values and exposure periods, the daily intake including dermal exposure is calculated as 0.24 mg/kg/day as the worst case. The lowest NOAEL of 0.26 mg/kg/day (rabbit inhalation study; Vedula *et al.*: 1995) was used to derive the margin of safety because the major exposure route at occupational place is expected to be inhalation.

$$0.26 \text{ mg/kg/day} / 0.24 \text{ mg/kg/day} = 1.08 < 100$$

Consumer exposure

Consumer exposure is expected to be low because of its use pattern.

Indirect exposure via environment (Japanese scenario)

As for indirect exposure via environment, PEC_{local} of 8.9×10^{-3} mg/l from local exposure scenario was used for the estimation. The daily intakes through drinking water and fish are calculated as 2.97×10^{-4} mg/kg/day and 1.34×10^{-5} mg/kg/day, respectively. The NOAEL of 10 mg/kg/day (rat oral study; MHW, Japan: 1997) was used to derive the margin of safety.

For drinking water

$$10 \text{ mg/kg/day} / 2.97 \times 10^{-4} \text{ mg/kg/day} = 3.36 \times 10^4 > 100$$

For fish

$$10 \text{ mg/kg/day} / 1.34 \times 10^{-5} \text{ mg/kg/day} = 7.46 \times 10^5 > 100$$

REVISED OECD HPV FORM 1

SIDS DOSSIER

ON THE HPV PHASE 5 CHEMICAL

Glycidyl methacrylate

CAS No. 106-91-2

Sponsor Country: Japan and United States

DATE: December 1, 1999

*3.5 BIODEGRADATION

Type: aerobic ; anaerobic

Inoculum: adapted ; non-adapted

Concentration of the chemical: related to COD ; DOC ; test substance

Medium: water ; water-sediment ; soil ; sewage treatment

Degradation: 94 % by BOD after 28 days

96 % by TOC after 28 days

100 % by GC after 28 days

Results: readily biodeg. ; inherently biodeg. ; under test condition no biodegradation observed , other

Method: OECD TG 301C

GLP: Yes No ?

Test substance: purity: > 95.0 %

Reference: MITI, Japan

4. ECOTOXICITY

***4.1 ACUTE/PROLONGED TOXICITY TO FISH**

- (a) Type of test: static []; semi-static [X]; flow-through []; other (*e.g. field test*) []
 open-system []; closed-system [X]
 Species: Medaka (*Oryzias latipes*)
 Exposure period: 96 h
 Results: LC₅₀ (24h) = 12.9 mg/l
 LC₅₀ (48h) = 5.7 mg/l
 LC₅₀ (72h) = 5.7 mg/l
 LC₅₀ (96h) = 3.7 mg/l
 Analytical monitoring: Yes [X] No [] ? []
 Method: OECD TG 203 (1992)
 GLP: Yes [X] No [] ? []
 Test substance: As prescribed by 1.1 - 1.4, purity: 97.9%
 Remarks: Groups of ten Medaka were placed to nominal concentrations of 1.0, 2.0, 4.0, 8.0 and 16 mg/l, and dechlorinated tap water as control. Test water was exchanged with freshly prepared one every 24h. The measured concentrations were between 103 and 118% of the nominal concentrations throughout the test period. Toxicity data were calculated based on the nominal concentrations.
 Reference: Environment Agency of Japan (1996)
- (b) Type of test: static []; semi-static []; flow-through [X]; other (*e.g. field test*) []
 open-system []; closed-system [X]
 Species: Medaka (*Oryzias latipes*)
 Exposure period: 14 d
 Results: LC₅₀ (14d) = 1.9 mg/l
 Analytical monitoring: Yes [X] No [] ? []
 Method: OECD TG 203 (1992)
 GLP: Yes [X] No [] ? []
 Test substance: As prescribed by 1.1 - 1.4, purity: 97.9 %
 Remarks: Groups of ten Medaka were placed to nominal concentrations of 0.49, 1.20 and 3.0 mg/l, and dechlorinated tap water as control. The measured concentrations were between 83 and 106 % of the nominal concentrations throughout the test period. Toxicity data was calculated based on the nominal concentrations.
 Reference: Environment Agency of Japan (1996)

4.2 ACUTE TOXICITY TO AQUATIC INVERTEBRATES***A. Daphnia**

- Type of test: static []; semi-static [X]; flow-through []; other (*e.g. field test*) [];
 open-system [X]; closed-system []
 Species: *Daphnia magna*.
 Exposure period: 48 h
 Results: EC₅₀ (24 h) = 42.3 mg/l
 EC₅₀ (48 h) = 24.9 mg/l
 Analytical monitoring: Yes [X] No [] ? []
 Method: OECD TG 202
 GLP: Yes [X] No [] ? []

Test substance: As prescribed by 1.1 - 1.4, purity: 97.9 %
 Remarks: 20 daphnids (4 replicates of 5 organisms) were placed to nominal concentrations of 10, 18, 32, 56 and 100 mg/l, and dechlorinated tap water. The EC₅₀ (48h) was determined based on the nominal concentrations. Measured concentrations at the start of exposure and after 48h were between 108-111% and between 88-90% of the nominal concentrations, respectively.
 Reference: Environment Agency of Japan (1995).

*4.3 TOXICITY TO AQUATIC PLANTS, e.g. algae

Species: *Selenastrum capricornutum* ATCC 22662
 Endpoint: Biomass [X]; Growth rate []; Other []
 Exposure period: 72 h
 Results: Biomass EC₅₀ (72h) = 14.6 mg/l
 (Endpoint) NOEC = 3.20 mg/l
 Analytical monitoring: Yes [X] No [] ? []
 Method: OECD TG 201 (1984)
 open-system [X]; closed-system []
 GLP: Yes [X] No [] ? []
 Test substance: As prescribed by 1.1 - 1.4, purity: 97.9 %
 Remarks: Static test. Biomass change (% inhibition) was measured in five nominal concentrations (1.6, 3.2, 6.4, 13.0, 25.0 and 50.0 mg/l). No solubilizer was used. EC₅₀ was calculated based on the nominal concentrations irrespective of measured concentrations ranging from 50-57% of the nominal concentrations after 72 h. EC₅₀ and NOEC calculated by the submitter using the time-weighted mean of measured concentrations are 9.2 and 2.4 mg/l, respectively.
 Reference: Environment Agency of Japan (1995)

4.4 TOXICITY TO BACTERIA

No data

4.5 CHRONIC TOXICITY TO AQUATIC ORGANISMS

4.5.1 CHRONIC TOXICITY TO FISH

No data

(*4.5.2 CHRONIC TOXICITY TO AQUATIC INVERTEBRATES

Type of test: static []; semi-static [X]; flow-through []; other (e.g. field test) [];
 open-system [X]; closed-system []
 Species: *Daphnia magna*.
 Endpoint: Mortality []; Reproduction rate [X]; Other [X]
 Results: Reproduction rate: EC₅₀ (21 d) = 3.18 mg/l
 (Endpoint) NOEC = 1.02 mg/l
 LOEC = 3.18 mg/l
 Analytical monitoring: Yes [X] No [] ? []
 Method: OECD TG 202 (1984)

GLP: Yes [**X**] No [] ? []
 Test substance: As prescribed by 1.1 - 1.4, purity: 97.9 %
 Remarks: 40 daphnids (4 replicate; 10 daphnids per replicate) were placed to five nominal concentrations (0.50, 1.5, 3.5, 9.5, 25.0 mg/l) and dechlorinated tap water as control (pH: 7.6 to 8.1; Hardness: 65 mg/l). Solubilizer was not used. Concentrations measured after 2 or 3 days, when test water was renewed through 21d test, were between 25-70% of the nominal concentrations, thus, toxicity data were calculated based on the time-weighted mean of measured concentrations.
 Reference: Environment Agency of Japan (1995).

5.1.2 ACUTE INHALATION TOXICITY

(a)

Type: LC₀ [X]; LC₁₀₀ []; LC₅₀ []; LCL₀ []; Other []

Species/strain: Rats/ Fischer 344

Exposure time: 4 hours

Value: See Remarks

Method: OECD TG 403 (5 males and 5 females at each dose level)

GLP: Yes [X] No [] ? []

Test substance: Purity: 99.8 %

Remarks: The highest concentration was the maximum practically attainable concentration and lower concentrations were run due to eye effects observed at higher concentrations. At nominal concentrations of 412 ppm (2,394 mg/m³) and 269 ppm (1,563 mg/m³), weight losses up to 15 %, labored breathing and eye irritation was observed. At 105 ppm (610 mg/m³), a 3 % decrease in body weight occurred. Corneal opacity was produced at all exposure concentrations (moderate at 412 and 269 ppm, slight at 105 ppm) and did not heal within 14 days post-exposure. There was no mortality observed at any concentration, including 412 ppm, the highest practically attainable vapor concentration.

5.2 CORROSIVENESS/IRRITATION

5.2.1 SKIN IRRITATION/CORROSION

(a)

Species/strain: Rabbits (domestic)
 Results: Highly corrosive ; Corrosive ; Highly irritating ;
 Irritating ; Moderate irritating ; Slightly irritating ;
 Not irritating
 Classification: Irritating ; Not irritating ; Risk of serious damage to eyes
 Method: Other
 GLP: Yes No ?
 Test substance: Purity: 92 %
 Remarks: One piece of undamaged skin two by two centimetres on either side of the spine was chosen for the testing, one side for testing and the other for control (an equal amount of tap water). 0.1 ml of original concentration of glycidyl methacrylate was applied for five days. The localized skin reaction was observed daily. After the experiments, the skin was removed for microscopic examination.

After application for one or two days, the test areas turned red, swelled and blistered. After three days, there was subdermal bleeding and ulcers. After five days the skin turned hard, become thicker and cracked, and there was pigmentation. The tissue pathological changes included degeneration and necrosis of surface skin cells, disappearance of cellular boundaries, displaying pink staining material, bleeding in the corium cells and lymph cell infiltration with accompanying formation of abscesses.

|------------|--|
| Remarks: | Undiluted glycidyl methacrylate was instilled directly into the eye of rabbits. |
| | Moderate to severe irritation and corneal damage was induced. Corneal damage did not heal within 7 days post-dosing. This ocular damage was prevented by washing with water within 30 seconds. |
| Reference: | Olson: 1960, Smyth: 1969 |

5.3 SKIN SENSITISATION

| | |
|-----------------|--|
| (a) | |
| Type: | Delayed allergy reaction test |
| Species/strain: | Hartley guinea pigs (male) |
| Results: | Sensitizing <input checked="" type="checkbox"/> ; Not sensitizing <input type="checkbox"/> ; Ambiguous <input type="checkbox"/> |
| Classification: | Sensitizing <input type="checkbox"/> ; Not sensitizing <input type="checkbox"/> |
| Method: | Modified Buehler method |
| GLP: | Yes <input type="checkbox"/> No <input type="checkbox"/> ? <input checked="" type="checkbox"/> |
| Test substance: | Purity: Unknown |
| Remarks: | 10 animals received three topical applications on the left side with 0.4 ml of 10 or 25 % glycidyl methacrylate in dipropylene glycol monomethyl ether (DPGME) during the three week induction phase. The animals with slight erythema on the dermal test site after the second application received the third application at lower concentration. The applications were removed after a six-hour exposure period. After a two-week rest period, the single challenge application was conducted to the right side of the animals in the same manner as the induction applications. The animals with slight erythema on the dermal test site after the third induction exposure received a 1 % solution of glycidyl methacrylate in DPGME. As positive control (10 animals), DER 331 epoxy resin in DPGME was used. |
| | During the challenge phase, slight erythema at the application site was observed in 7/10 animals treated with glycidyl methacrylate. In positive control group, 8/10 animals showed the same change. |

| Test substance: | Purity: 92 % |
| Remarks: | The hair of animals was removed and a patch of skin two by two centimetres on either side of the spine was chosen for testing. One side for testing and the other for control. Localized smear application (to 10 animals) or intradermal injection (to 10 animals) with 0.1 ml of 1 % glycidyl methacrylate in acetone was conducted to the animals for |

ten days, and after 21 days they were excited and the localized reactions were observed.

Hyperemia, edema, scleroma and necrosis were observed on the treated area and these changes reached a peak on the fourth day. But no obvious change was observed on the control area. Using the evaluation standards of rating the intensity of delayed reactions, the skin smear allergic intensity was 14 and the intradermal injection intensity was 13, both belonging to the strong allergenic category.

Reference: Ou-Yang *et al.*: 1988

(c)

Type: Rapid allergic reaction test (active stimulation)

Species/strain: Guinea pigs

Results: Sensitizing ; Not sensitizing ; Ambiguous

Classification: Sensitizing ; Not sensitizing

Method: Other

GLP: Yes No ?

Test substance: Purity: 92 %

Remarks: The hair of animals was removed and a patch of skin two by two centimetres was chosen for testing. Intradermal injection of 0.5 % glycidyl methacrylate solution with homologous serum albumin was conducted to 8 animals for ten days. After 21 days, the same solution was injected intravenously to 5 of these 8 animals and the reactions were observed. As control, homologous serum albumin with no antibodies was injected to 3 other animals.

Breathing difficulties, wheezing, increased mouth and nose secretions, spasms and death were observed in the test group, but no obvious changes in the control group. In accordance with the rapid allergic reaction strength category standards, the reaction intensity was evaluated as 13, which belongs to the strong allergenic category.

Reference: Ou-Yang *et al.*: 1988

(d)

Type: Rapid allergic reaction test (passive stimulation)

Species/strain: Guinea pigs

Results: Sensitizing ; Not sensitizing ; Ambiguous

Classification: Sensitizing ; Not sensitizing

Method: Other

GLP: Yes No ?

Test substance: Purity: 92 %

Remarks: The blood of three animals, which were already allergic, was removed and placed in a centrifuge, and serum was extracted and diluted one part to three, one part to ten and one part to thirty with biological saline solution. The hair of other five animals was removed, and four pieces of skin two by two centimetres was chosen for testing. 0.1 ml of saline solution (control), or one to three solution, one to ten solution or one to thirty solution of serum saline solution was injected under the skin. One hour later, 0.5 ml of 0.1 % glycidyl methacrylate

homologous serum albumin solution and 0.4 ml of saline solution was injected intravenously, and the localized reactions were observed.

Blue circles or spots were observed most markedly in the one to three areas, followed by the one to ten area and in the one to thirty areas, and there were a few scattered blue spots. This showed that the reaction is related to the dosage. Evaluating these reactions in accordance with the rapid allergic reaction strength category standards, they belong to the strong allergic category.

*5.4 REPEATED DOSE TOXICITY

(a)

Test Substance Glycidyl methacrylate
Produced by Japan Oil Ltd, Lot No. 50905Y, Purity: 99.93 %, Kept at cold and closed dark place until use

Method

Method: OECD TG 422

Test type: Combined Repeat Dose and Reproductive/Developmental Toxicity Screening Test

GLP: Yes

Year: 1997

Species: Rats

Strain: Cij; CD (SD)

Route of administration: Oral (by gavage)

Duration of test: Males; 46 days
Females; 40 - 47 days

Doses: 10, 30, 100 mg/kg/day (in corn oil)

Sex: Male/Female

Exposure period: Males; 45 days,
Females; from 14 days before mating to day 3 of lactation

Frequency of treatment: Daily

Control group and treatment: Concurrent vehicle

Post exposure observation period: 1 day

Statistical analysis: Multi-comparison analysis for continuous data and Fisher's exact test for quantal data

Test condition: Age at study initiation was 10 weeks old (males: 382-414 g, females: 245-282 g). Number of animals per sex per dose was 12. Functional

observation was not performed because the test was conducted by the Test Guideline adopted in 1990.

Results

NOAEL: 10 mg/kg/day for males, 30 mg/kg/day for females

LOAEL: 30 mg/kg/day for males, 100 mg/kg/day for females

Toxic effects: Male:

At 30 mg/kg:

Salivation at day 25 to day 40 of administration in 5 of 12 animals (This symptom disappeared within 10 minutes after the appearance)

Squamous hyperplasia in forestomach (0: 1/12, 10 mg/kg: 1/11, 30 mg/kg: 11/12, 100 mg/kg: 11/11)

At 100 mg/kg:

Salivation continuously after 19 days of administration in all animals (This symptom were observed immediately after administration and almost disappeared within 30 minutes)

Increase in absolute and relative kidney and adrenal weights
Increase in total protein and albumin

Squamous hyperplasia in forestomach

Female:

At 100 mg/kg:

Cellular infiltration in forestomach ((0: 0/12, 10 mg/kg: 2/12, 30 mg/kg: 3/12, 100 mg/kg: 4/12)

Remarks: Two males died at 10 mg/kg on day 21 of administration and at 100 mg/kg on day 26 of administration, respectively.

Although the reason of two males' death was not clear, authors concluded it might be no chemical-related.

Salivation and increased serum protein in males was not considered as adverse effects.

Histological change observed in forestomach was considered to be due to irritation of this chemical.

Conclusions

Repeated dose toxicity in rats by oral administration is hyperplasia in forestomach and NOAEL is 10 mg/kg/day.

Data Quality

Species/strain: Rabbits (domestic)
 Sex: Female ; Male ; Male/Female ; No data
 Route of Administration: Oral
 Exposure period: 15 days
 Frequency of treatment: Daily
 Post exposure observation period:
 Dose: 50 mg/kg/day
 Control group: Yes ; No ; No data ; Vehicle: Peanut oil
 Concurrent no treatment ; Concurrent vehicle ; Historical
 NOAEL:
 LOAEL: Could not be evaluated
 Results: Fifteen days after treatment, slow reactions and some head shaking was observed in the treated group. In addition, 2 of 10 animals succumbed to prostration and died. There were decrease in body weight, increase in relative weights of heart, liver and kidneys, and some hematological changes (increase in white blood cells, platelets and lymph cells, decrease in leukoplasts and intermediate cells). In pathological examination, there was heart bleeding, deterioration of the heart muscle fibers, widespread fatty changes in the liver with focal necrosis. In kidneys, extravasated blood and hemorrhaging were observed, and the upper part of the renal tubules was swollen. There was also red stained protein in the tubular cavity, cranial hemorrhaging, small focal necrosis of the gray matter, and ulceration and necrosis of the mucous membrane of the stomach. However, incidence of these changes was not reported.

Test Substance Glycidyl methacrylate
Supplied by the Dow Chemical Company, Identification # IL13016601, Purity: 99.5 %

Method

Method: Other
Test type: Thirteen-week vapor inhalation toxicity study
GLP: Yes
Year: 1996
Species: Rats
Strain: Fischer 344
Route of administration: Inhalation (vapor)
Duration of test: 13 weeks
Doses: 0.5, 2, 15 ppm (2.9, 12, 87 mg/m³, calculated daily dose: 0.35, 1.46, 10.59 mg/kg/day)
Sex: Male/Female
Exposure period: 13 weeks
Frequency of treatment: 6 hours/day, 5 days/week
Control group and treatment: Concurrent vehicle
Post exposure observation period: 1 day
Statistical analysis: Statistical significance by Dunnett's test or Wilcoxon Rank-Sum test with a Bonferroni correction for multiple comparisons
Test condition: Age at study initiation was 8 weeks old. Number of animals per sex per dose was 10.

This study was conducted to meet the Standard Operating Procedures of the Toxicology Research Laboratory and many Good Laboratory Practice Standards. Permanent records of all data generated during the course of the study, the protocol, any addenda to the protocol and a copy of the final report were available for inspection by the Quality Assurance Unit of Health and Environmental Sciences, The Dow Chemical Company.

Results

NOAEL: 12 mg/m³ (1.46 mg/kg/day)
LOAEL: 87 mg/m³ (10.59 mg/kg/day)
Toxic effects: Male:

At 87 mg/m³

Hyperplasia of respiratory epithelium of the nasal tissues, graded as very slight, in all animals. The hyperplastic respiratory epithelium was approximately two to three times as thick as that of control animals, and was located in the anterior portions of the nasal passages, involving the tips of the turbinates and the lateral walls of the nasal passages.

Female:

At 87 mg/m³

Hyperplasia of respiratory epithelium of the nasal tissues, graded as very slight, in all animals. The hyperplastic respiratory epithelium was approximately two to three times as thick as that of control animals, and was located in the anterior portions of the

nasal passages, involving the tips of the turbinates and the lateral walls of the nasal passages.

Remarks: There were no treatment related in-life observations, and no significant treatment-related effects on body weight, urinalysis, clinical chemistry or hematology parameters, as well as gross pathologic changes or organ weights at any exposure levels.

The changes observed in respiratory tract were likely resulted from the irritation of glycidyl methacrylate.

Conclusions Repeated dose toxicity in rats by inhalation is hyperplasia in nasal tissues and NOAEL is 2 ppm (equivalent to 1.46 mg/kg/day).

Data Quality Valid with restriction because of unspecified Test Guideline and unpublished

| | |
|-----------------------|---|
| Type: | Analysis of the phenotype and the restriction enzyme mapping level of mutations |
| System of testing: | <i>Escherichia coli</i> HB 101 |
| Concentration: | 0.1, 0.3, 1.0 mmol/l |
| Metabolic activation: | With []; Without []; With and Without []; No data [X] |
| Results: | The transformation efficiency of glycidyl methacrylate-bound pBR322 was much lower than that of pBR322 alone. Glycidyl methacrylate-bound pBR322 induced phenotype changes in competent cells (i.e., tetracycline-resistance inactivation or ampicillin-resistance inactivation). There were two mutants of pBR322, ApRTcS and ApSTcR, in the transformants and a deductive mutant ApsTcs in the nontransformants. All of the selected mutants were stable and heritable. When restriction enzyme maps were used to analyze the mutant ApRTcS, four of seven maps were changed, some sites were shifted to other resistant gene regions, for example, sites of Bg/I, EcoRI, HindIII, HincII, etc., and there was a new recognition site for HincII (252). No DNA fragment insertion or deletion was observed on any maps. |

| Remarks: | Plasmid pBR322 was used for <i>in vitro</i> binding, mutant screening, and restriction enzyme mapping. The binding between glycidyl methacrylate and DNA <i>in vitro</i> has been verified by means of a spectrophotometric method. These results suggest that when glycidyl methacrylate is covalently linked to the plasmid DNA, it gives rise to a premutagenic lesion of DNA that is converted <i>in vivo</i> into a point mutation. |

Remarks: Structural chromosomal aberrations (including gap) and polyploidy were induced. However, a trend test showed no dose-dependency for the induction of polyploidy with the 24 hours continuous treatment and the short-term treatment with the metabolic activation system.

Conclusions Structural chromosome aberration of CHL/IU cells is positive with and without metabolic activation.

System of testing: Golden Syrian hamster embryo cells (diploid)

Concentration: 0.9 - 14.2 mg/L

Metabolic activation: With ; Without ; With and Without ; No data

S9:

Results: Transformation was induced. Cells in a transformed focus exhibited 3-dimensional growth and crossing-over the periphery of the focus. These cells had an increased nucleus to cytoplasm ratio and were more basophilic usually. In addition, there were also further evidences for the cell transformation, including the agglutinability following exposure to concanavalin A and colony formation on the soft agar medium.

* 5.6 GENETIC TOXICITY IN VIVO

(a)

Test Substance Glycidyl methacrylate
 Produced by Japan Oil Ltd., Lot No. 50905Y, Purity: 99.93 %

Method

Method: Guidelines for Screening Mutagenicity Testing of Chemicals (Japan) and OECD TG 474
 Test type: Micronucleus test
 GLP: Yes
 Year: 1997
 Species: Mice
 Strain: Crj: BDF1
 Sex: Male/Female
 Route of administration: Oral (a single dose by gavage)
 Doses: Male: 188, 375 and 750 mg/kg
 Female: 250, 500 and 1,000 mg/kg
 Exposure period: 48 hours
 Statistical methods: Fisher's exact test with a Bonferroni correction for multiple comparisons
 Test conditions: Age at study initiation was 9 weeks old. Number of animals per sex per dose was 5. Three samples were collected from each animal at 48 hour after administration.
 Solvent: Olive oil
 Negative control: vehicle
 Positive controls: Cyclophosphamide (50 mg/kg)

Results

Genotoxic effects: + ? -

 Remarks: The frequency of micronucleated polychromatic erythrocytes was significantly increased in both sexes at the highest doses (750 mg/kg for male and 1,000 mg/kg for female), compared to control. In

addition, it showed a significant tendency to increase with dose-dependency. Inhibition of bone marrow cell proliferation was observed at the highest doses in both sexes under the test conditions.

Species/strain: Transgenic Big Blue® Fischer 344 rats

Sex: Female []; Male [X]; Male/Female []; No data []

Route of Administration: Inhalation

Exposure period: Unknown (6 hours/day, 5 days/week)

Doses: 1, 10, 25 ppm (5.82, 58.2, 145.5 mg/m³, calculated daily dose: 0.71, 7.08, 17.70 mg/kg/day)

Results: There were no statistically significant increases in the frequencies of *lacI* mutants in either the olfactory or respiratory epithelium of rats exposed to glycidyl methacrylate at 145.5 mg/m³, compared to the negative control group.

Effect on mitotic index or P/N ratio:

Genotoxic effects: + ? -
 [] [] [X]

Method: Other

GLP: Yes [] No [] ? [X]

Test substance: Purity: Unknown

Remarks: The induction of gene mutations at the *lacI* locus by glycidyl methacrylate was evaluated using transgenic Big Blue® Fischer 344 rats (15 rats/group).
After the last exposure, 3 rats/group were immediately sacrificed and gross pathological and histopathological examinations in the nasal epithelium were conducted. The remaining 12 rats/group were maintained under standard laboratory conditions for 4 weeks for the fixation and expression of induced DNA lesions into mutations. After this expression time, the rats were sacrificed, and various tissues were collected and stored. Individual genomic DNA samples were extracted from the olfactory epithelium of 5 rats/group. For respiratory epithelium, tissue samples from 3 individual animals within each group were pooled (4 pooled samples/group from 12 rats) for DNA extraction. Mutations in the target gene (*lacI*) were analyzed by recovering the shuttle vector from the genomic DNA, packaging into bacteriophage lambda (λ) and plating on indicator bacteria.

Histopathological lesions observed in the nasal epithelium of glycidyl methacrylate exposed rats justified the highest exposure concentration employed in the study.

5.7 CARCINOGENICITY

There was no available data.

*5.8 TOXICITY TO REPRODUCTION

(a)

Test Substance Glycidyl methacrylate
Produced by Japan Oil Ltd, Lot No. 50905Y, Purity: 99.93 %, Kept at cold and closed dark place until use

Method

Method: OECD TG 422
Test type: Combined Repeat Dose and Reproductive/Developmental Toxicity Screening Test
GLP: Yes
Year: 1997
Species: Rats
Strain: Cij; CD (SD)
Route of administration: Oral (by gavage)
Doses: 10, 30, 100 mg/kg/day (in corn oil)
Sex: Male/Female
Control group and treatment: Concurrent vehicle
Frequency of treatment: Daily
Duration of test: 40-47 days
Premating exposure period for males: 14 days
Premating exposure period for females: 14 days
Statistical analysis: Multi-comparison analysis for continuous data and Chai square test for quantal data
Test condition: Age at study initiation was 10 weeks old (males: 382-414 g, females: 245-282 g). Number of parents per sex per dose was 12. Male/female per cage was 1/1, length of cohabitation was 10 days at the longest, and proof of pregnancy was judged by sperm detection in vagina. Functional observation, sperm examination, measurement of anogenital distance and so on except estrous cycle length and pattern were not performed because the test was conducted by the TG adopted in 1990. As additional histological examination, observation of seminiferous epithelium cells in seminiferous tubule was conducted at 100 mg/kg because of low fertility observed.

Results

NOAEL: 30 mg/kg for parents and 100 mg/kg for F1 offsprings
Toxic effects: Parental toxicity:
At 100 mg/kg

The fertility index (number of delivered animals/ number of mated animals) dropped to 16.7 %, compared to 81.8 %, 100 % and 91.7 % at 0, 10 and 30 mg/kg, respectively. There were no effects on the estrous cycle, copulation index, or gestation length. No significant changes in the numbers of corpora lutea, implants, pups born and live pups as well as the implantation and delivery indices were observed. There were no significant differences in the gestation index, live birth index or viability index on day 4.

Histopathological analysis of the gonads showed no significant effect. No change in the number of gonocyte per Sertoli cell was observed in epithelium of seminiferous tubules (stage VIII) of all survival males at 100 mg/kg.

| | |
|--------------------------|--|
| Remarks: | <p>Toxicity to offspring: No abnormalities were noted in the body weights of live pups or on necropsy of pups of any treated group.</p> <p>Decrease of fertility index at 100 mg/kg was reproducible. There was a tendency for decrease in the number of corpora lutea, implants, pups born and live pups born, implantation index and delivery index at 100 mg/kg. However, these changes were not statistically significant.</p> |
| Conclusions | Reproductive toxicity in rats by oral administration is a decrease of fertility index and NOAEL is 30 mg/kg/day. |
| Data Quality | Valid without restriction |

*5.9 DEVELOPMENTAL TOXICITY/ TERATOGENICITY

(a)

Test Substance Glycidyl methacrylate
 Purity: 92 %

Method

Method: Other
 GLP: Unknown
 Year: 1988
 Species: Rats
 Strain: Wistar
 Route of administration: Oral (by gavage)
 Doses: 5.38, 10.76, 21.52, 108.0 mg/kg/day
 Sex: Female
 Exposure period: Day 5 to day 15 of gestation
 Frequency of treatment: Daily
 Control group and treatment: There was negative control, but no more data.
 Duration of test: 15 days
 Statistical methods: Unknown
 Test conditions: 93 pregnant rats (200 - 280 g) were divided into six groups with 14 to 18 animals in each group. The animals were sacrificed on the 19th day of pregnancy.
 Positive control: Phonetic (DIKUSHUANG in Chinese report) at 1.0 mg/kg.

Results

NOAEL Maternal Toxicity: 21.52 mg/kg/day

NOAEL teratogenicity: 108.0 mg/kg/day

Toxic effect: Maternal general toxicity

At 108.0 mg/kg:

Significant decrease in body weight gain

Pregnancy/litter data:

At 108.0 mg/kg:

A statistically significant increase in the fetal resorption rate (12.7 %, compared to 5.18 % of control group)

Foetal data:

No external, skeletal or organ abnormalities

No significant difference in body weight from the control

Remarks: The percentage of pups stillborn was somewhat higher than control at all dose levels (0 % for control, and 1.35 %, 7.58 %, 1.26 % and 6.03 % for treated group at 5.38, 10.76, 21.52 and 108.0 mg/kg/day, respectively). However, this change was not dose-dependent and statistically significant change was only at 10.76 mg/kg. This was not considered to be dose-related change.

| | |
|---------------------|---|
| Conclusions | Developmental toxicity in rats by oral administration is not observed at the highest dose, 108 mg/kg/day which induces maternal toxicity. |
| Data Quality | Valid with restriction because method and GLP are unknown |

| Frequency of treatment: | 7 hours/day, daily |
| Doses: | 0.5, 2, 10 ppm (2.91, 11.6, 58.2 mg/m ³ , calculated daily dose: 0.31, 1.22, 6.11 mg/kg/day) |
| Control group: | Yes <input checked="" type="checkbox"/> ; No <input type="checkbox"/> ; No data <input type="checkbox"/> ; Concurrent no treatment <input checked="" type="checkbox"/> ; Concurrent vehicle <input type="checkbox"/> ; Historical <input type="checkbox"/> |
| NOAEL Maternal Toxicity: | 2.91 mg/m ³ (0.31 mg/kg/day) |
| NOAEL teratogenicity: | 58.2 mg/m ³ (6.11 mg/kg/day) |
| Results: | Maternal general toxicity: |

The principal indication of maternal toxicity was inflammation of the nasal olfactory and respiratory epithelium at the 11.6 and 58.2 mg/m³.

Pregnancy/litter data:

Foetal data: There was no teratogenic effect.

Method: Other
 GLP: Yes [] No [] ? [X]
 Test substance: Purity: Unknown
 Remarks:

5.10 OTHER RELEVANT INFORMATION

A. Specific toxicities

Type: Neurotoxicity
 Results: 13-week inhalation neurotoxicity study was performed in Fischer 344 rats. At week 4, there was a low incidence of nasal discharge and enlarged nostrils at 3.9 and 12 mg/m³. There were no treatment-related effects in any of the other measures. There was no evidence of neurotoxic effects at any exposure level.
 Remarks: Fischer 344 rats were exposed by inhalation to glycidyl methacrylate at approximately 0.5, 2 or 15 ppm (2.9, 12, 87 mg/m³), 6 hours/day, 5 days/ week for 13 weeks (calculated daily dose: 0.35, 1.46, 10.59 mg/kg/day). The animals were weighted and clinically examined weekly. A functional observation battery (FOB) and motor activity (MA) were conducted preexposure and at the end of each month of exposure. In addition, the postexposure neurotoxicity evaluation focused on evoked potential testing of the visual (FEP), auditory (ABR), somatosensory system (SEP), and caudal nerves (CNAP), and a comprehensive neuropathological examination.
 References: Mattsson *et al.*: 1996

B. Toxicodynamics, toxicokinetics

Type: Toxicokinetics
 Results: Toxicokinetics of glycidyl methacrylate was investigated in rabbits. After an intravenous injection at 200 mg/kg, the concentration-time curve of this chemical could exactly fit the two-compartment open model, and over 95 % of the parent compound had disappeared from the blood within 10 minutes. Following a subcutaneous injection at 800 mg/kg, the toxicokinetics appeared to fit a first-order absorption one-compartment open model. This chemical was metabolized by a first-order process in incubation with whole blood, plasma, erythrocyte suspension, and homogenates of brain, heart, liver, lung, spleen, kidney, small intestine, and muscle. The highest rate of elimination had been found in blood and liver homogenate. The subcutaneous co-administration of tri-*o*-cresyl-phosphate (an carboxylesterase inhibitor) with this chemical resulted in about a ten-fold increase in the maximum blood concentrations of this chemical, compared to those of animals dosed with this chemical alone. *In*

| | |
|-------------|--|
| Remarks: | <i>vitro</i> , elimination rate could be also decreased by tri-o-cresyl phosphate. |
| References: | Shi Tao <i>et al.</i> : 1988 |
| Type: | Toxicokinetics |
| Results: | |
| Remarks: | The metabolism of glycidyl methacrylate in mammals will likely proceed by at least two different and competing enzyme systems, epoxide hydratase and non-specific carboxylesterases. Species differences in the activity of these enzymes suggest that the carboxylesterase route of metabolism may predominate in the nasal tissue of rabbits (yielding glycidol and methacrylic acid) whereas the epoxide hydratase route would likely predominate in rats and humans (producing glycerol methacrylate, then glycerol and methacrylic acid by carboxylesterase). |

* 5.11 EXPERIENCE WITH HUMAN EXPOSURE

A. Sensitization

| | |
|-----------------|---|
| (a) | |
| Type: | Patch test |
| Results: | Sensitizing <input checked="" type="checkbox"/> ; Not sensitizing <input type="checkbox"/> ; Ambiguous <input type="checkbox"/> |
| Classification: | Sensitizing <input type="checkbox"/> ; Not sensitizing <input type="checkbox"/> |
| Method: | Other |
| GLP: | Yes <input type="checkbox"/> No <input type="checkbox"/> ? <input checked="" type="checkbox"/> |
| Test substance: | purity: unknown |
| Remarks: | Three cases of allergic contact hypersensitivity to glycidyl methacrylate used in adhesive sealant manufacturing were reported. Both closed and open patch testing with 1% glycidyl methacrylate solution in petrolatum was positive in all 3 cases. Symptoms included erythema, edema, and vesiculation and a strong 2+ reaction as scored according to the International Contact Dermatitis Research Group classification |
| Reference: | Dempsey: 1982 |
| (b) | |
| Type: | Patch test |
| Results: | Sensitizing <input checked="" type="checkbox"/> ; Not sensitizing <input type="checkbox"/> ; Ambiguous <input type="checkbox"/> |
| Classification: | Sensitizing <input type="checkbox"/> ; Not sensitizing <input type="checkbox"/> |
| Method: | Other |
| GLP: | Yes <input type="checkbox"/> No <input checked="" type="checkbox"/> ? <input type="checkbox"/> |
| Test substance: | purity: unknown |
| Remarks: | Patch test was conducted for a 31-year-old non-atopic woman, who had worked as a chemist and mixed emulsions used to impregnate paper and textile materials to make them oil and water resistant. In this work, she had been in contact with acrylate derivatives (glycidyl methacrylate, ethoxyethyl acrylate etc.). In relation to this work, she |

had a history of recurrent acute vesiculopapular hand dermatitis with severe itching and burning mainly on the fingertips, palmar and dorsal aspects of the fingers, and both palms. As a result of patch test, she reacted only to nickel, glycidyl methacrylate (0.01 and 0.05 % acet.) and ethoxyethyl acrylate among the European standard series and (meth) acrylate series. This reaction to nickel was relevant to her jewelry intolerance.

; Summary - THE FOLLOWING CHEMICAL IS INCLUDED ON A LIST OF CHEMICALS

AND MIXTURES FOR WHICH REPORTING IS CURRENTLY REQUIRED UNDER THE TOXIC SUBSTANCES CONTROL ACT SECTION 2607A. THIS TOXIC SUBSTANCE IS SUBJECT TO PRELIMINARY ASSESSMENT INFORMATION RULES ON PRODUCTION QUANTITIES, USES, EXPOSURES, AND ADVERSE EFFECTS. MANUFACTURERS INCLUDING IMPORTERS MUST SUBMIT A REPORT FOR THIS LISTED CHEMICAL MANUFACTURED AT EACH SITE.

entry date: OCT 1991 effective date: 1982

THE SUBSTANCE IS INCLUDED IN THE LIST OF MONOMERS AND OTHER STARTING SUBSTANCES, WHICH MAY CONTINUE TO BE USED FOR THE MANUFACTURE OF PLASTICS AND ARTICLES INTENDED TO COME INTO CONTACT WITH FOODSTUFFS UNTIL 1 JANUARY 1997 PENDING A DECISION ON THEIR INCLUSION IN THE LIST OF AUTHORIZED SUBSTANCES. THE USE OF THE SUBSTANCE IS SUBJECT TO THE RESTRICTIONS SPECIFIED THEREIN. PLASTIC MATERIALS AND ARTICLES SHALL NOT TRANSFER THEIR CONSTITUENTS TO FOODSTUFFS IN QUANTITIES EXCEEDING 10MG/DM2 OF SURFACE AREA OF MATERIAL OR ARTICLE OR 60 MG/KG OF FOODSTUFFS IN THE SPECIFIED CASES. VERIFICATION OF COMPLIANCE WITH THE MIGRATION LIMITS SHALL BE CARRIED OUT IN ACCORDANCE WITH DIRECTIVES 82/711/EEC AND 85/572/EEC.
